Trees

1

What is a Tree

- In computer science, a tree is an abstract model of a hierarchical structure
- A tree consists of nodes with a parent-child relation
- Applications:
 - Organization charts
 - File systems
 - Programming environments

```
graph TD; A[Computers'R'Us] --> B[Sales]; A --> C[Manufacturing]; A --> D[R&D]; B --> E[US]; B --> F[International]; C --> G[Laptops]; C --> H[Desktops]; F --> I[Europe]; F --> J[Asia]; F --> K[Canada];
```

Trees

2

Tree Terminology

- Root: node without parent (A)
- Internal node: node with at least one child (A, B, C, F)
- External node (a.k.a. leaf): node without children (E, I, J, K, G, H, D)
- Ancestors of a node: parent, grandparent, grand-grandparent, etc.
- Depth of a node: number of ancestors
- Height of a tree: maximum depth of any node (3)
- Descendant of a node: child, grandchild, grand-grandchild, etc.

```
graph TD; A[A] --> B[B]; A --> C[C]; B --> E[E]; B --> F[F]; C --> G[G]; C --> H[H]; F --> I[I]; F --> J[J]; F --> K[K];
```

Trees

subtree³

Tree ADT

- We use positions to abstract nodes
- Generic methods:
 - Integer `len()`
 - Boolean `is_empty()`
 - Iterator `positions()`
 - Iterator `iter()`
- Accessor methods:
 - position `root()`
 - position `parent(p)`
 - Iterator `children(p)`
 - Integer `num_children(p)`
- ◆ Query methods:
 - Boolean `is_leaf(p)`
 - Boolean `is_root(p)`
- ◆ Update method:
 - element `replace(p, o)`
- ◆ Additional update methods may be defined by data structures implementing the Tree ADT

Abstract Tree Class in Python

```
class Tree:
    """Abstract base class representing a tree structure."""
    #----- nested Position class -----
    class Position:
        """An abstraction representing the location of a single element."""
        def element(self):
            """Return the element stored at this Position."""
            raise NotImplementedError('must be implemented by subclass')
        def __eq__(self, other):
            """Return True if other Position represents the same location."""
            raise NotImplementedError('must be implemented by subclass')
        def __ne__(self, other):
            """Return True if other does not represent the same location."""
            return not (self == other)
        @opposite of __eq__

    #----- abstract methods that concrete subclass must support -----
    def root(self):
        """Return Position representing the tree's root (or None if empty)."""
        raise NotImplementedError('must be implemented by subclass')
    def parent(self, p):
        """Return Position representing p's parent (or None if p is root)."""
        raise NotImplementedError('must be implemented by subclass')
    def num_children(self, p):
        """Return the number of children that Position p has."""
        raise NotImplementedError('must be implemented by subclass')
    def children(self, p):
        """Generate an iteration of Positions representing p's children."""
        raise NotImplementedError('must be implemented by subclass')
    def __len__(self):
        """Return the total number of elements in the tree."""
        raise NotImplementedError('must be implemented by subclass')

    #----- concrete methods implemented in this class -----
    def is_root(self, p):
        """Return True if Position p represents the root of the tree."""
        return self.root() == p
    def is_leaf(self, p):
        """Return True if Position p does not have any children."""
        return self.num_children(p) == 0
    def is_empty(self):
        """Return True if the tree is empty."""
        return len(self) == 0
```

```
20 #----- abstract methods that concrete subclass must support -----
21 def root(self):
22     """Return Position representing the tree's root (or None if empty)."""
23     raise NotImplementedError('must be implemented by subclass')
24
25 def parent(self, p):
26     """Return Position representing p's parent (or None if p is root)."""
27     raise NotImplementedError('must be implemented by subclass')
28
29 def num_children(self, p):
30     """Return the number of children that Position p has."""
31     raise NotImplementedError('must be implemented by subclass')
32
33 def children(self, p):
34     """Generate an iteration of Positions representing p's children."""
35     raise NotImplementedError('must be implemented by subclass')
36
37 def __len__(self):
38     """Return the total number of elements in the tree."""
39     raise NotImplementedError('must be implemented by subclass')
40
41 #----- concrete methods implemented in this class -----
42 def is_root(self, p):
43     """Return True if Position p represents the root of the tree."""
44     return self.root() == p
45
46 def is_leaf(self, p):
47     """Return True if Position p does not have any children."""
48     return self.num_children(p) == 0
49
50 def is_empty(self):
51     """Return True if the tree is empty."""
52     return len(self) == 0
```

Preorder Traversal

- A traversal visits the nodes of a tree in a systematic manner
 - In a preorder traversal, a node is visited before its descendants
 - Application: print a structured document
- Algorithm *preOrder(v)***
visit(v)
for each child *w* of *v*
preorder(w)

Postorder Traversal

- In a postorder traversal, a node is visited after its descendants
 - Application: compute space used by files in a directory and its subdirectories
- Algorithm *postOrder(v)***
for each child *w* of *v*
postOrder(w)
visit(v)

Binary Trees

- A binary tree is a tree with the following properties:
 - Each internal node has at most two children (exactly two for **proper** binary trees)
 - The children of a node are an ordered pair
- We call the children of an internal node **left child** and **right child**
- Alternative recursive definition: a binary tree is either
 - a tree consisting of a single node, or
 - a tree whose root has an ordered pair of children, each of which is a binary tree

- Applications:
 - arithmetic expressions
 - decision processes
 - searching

Arithmetic Expression Tree

- Binary tree associated with an arithmetic expression
 - internal nodes: operators
 - external nodes: operands
- Example: arithmetic expression tree for the expression $(2 \times (a - 1) + (3 \times b))$

Decision Tree

- Binary tree associated with a decision process
 - internal nodes: questions with yes/no answer
 - external nodes: decisions
- Example: dining decision

Properties of Proper Binary Trees

Notation

n number of nodes
 e number of external nodes
 i number of internal nodes
 h height

Properties:

- $e = i + 1$
- $n = 2e - 1$
- $h \leq i$
- $h \leq (n - 1)/2$
- $e \leq 2^h$
- $h \geq \log_2 e$
- $h \geq \log_2 (n + 1) - 1$

BinaryTree ADT

- The BinaryTree ADT extends the Tree ADT, i.e., it inherits all the methods of the Tree ADT
- Update methods may be defined by data structures implementing the BinaryTree ADT
- Additional methods:
 - position **left**(p)
 - position **right**(p)
 - position **sibling**(p)

Inorder Traversal

- In an inorder traversal a node is visited after its left subtree and before its right subtree
- Application: draw a binary tree
 - $x(v)$ = inorder rank of v
 - $y(v)$ = depth of v

```
Algorithm inOrder( $v$ )
  if  $v$  has a left child
    inOrder(left( $v$ ))
  visit( $v$ )
  if  $v$  has a right child
    inOrder(right( $v$ ))
```

Print Arithmetic Expressions

- Specialization of an inorder traversal
 - print operand or operator when visiting node
 - print "(" before traversing left subtree
 - print ")" after traversing right subtree

```
Algorithm printExpression( $v$ )
  if  $v$  has a left child
    print("(")
    inOrder(left( $v$ ))
  print( $v$ .element())
  if  $v$  has a right child
    inOrder(right( $v$ ))
    print(")")
```

$((2 \times (a - 1)) + (3 \times b))$

Evaluate Arithmetic Expressions

- Specialization of a postorder traversal
 - recursive method returning the value of a subtree
 - when visiting an internal node, combine the values of the subtrees

```
Algorithm evalExpr( $v$ )
  if is_Leaf( $v$ )
    return  $v$ .element()
  else
     $x \leftarrow \text{evalExpr}(\text{left}(\mathbf{v}))$ 
     $y \leftarrow \text{evalExpr}(\text{right}(\mathbf{v}))$ 
     $\diamond \leftarrow$  operator stored at  $v$ 
    return  $x \diamond y$ 
```

Euler Tour Traversal

- Generic traversal of a binary tree
- Includes a special cases the preorder, postorder and inorder traversals
- Walk around the tree and visit each node three times:
 - on the left (preorder)
 - from below (inorder)
 - on the right (postorder)

Linked Structure for Trees

- A node is represented by an object storing
 - Element
 - Parent node
 - Sequence of children nodes
- Node objects implement the Position ADT

Linked Structure for Binary Trees

- A node is represented by an object storing
 - Element
 - Parent node
 - Left child node
 - Right child node
- Node objects implement the Position ADT

Array-Based Representation of Binary Trees

- Nodes are stored in an array A

- Node v is stored at $A[\text{rank}(v)]$
 - $\text{rank}(\text{root}) = 1$
 - if node is the left child of parent(node),
 $\text{rank}(\text{node}) = 2 \cdot \text{rank}(\text{parent}(\text{node}))$
 - if node is the right child of parent(node),
 $\text{rank}(\text{node}) = 2 \cdot \text{rank}(\text{parent}(\text{node})) + 1$
